this is the secondary research done for why similar apps like food panda by ola and uber eats by uber failed

Use this as the **single master prompt for Claude**. It is designed so Claude does not just create charts—it audits the repo, determines what evidence is actually usable, computes the metrics from source data, and builds a coherent executive dashboard story.

You are the EXECUTION LEAD, DATA ANALYST, MARKET-RESEARCH LEAD, PRODUCT STRATE 

You have access to the COMPLETE EXISTING PROJECT REPOSITORY.

Your job is NOT to give me recommendations for what dashboards I could create.

YOUR JOB IS TO ACTUALLY:

1. inspect the repository,
2. understand every relevant research artifact,
3. clean and analyse the available data,
4. calculate defensible KPIs and derived marketing metrics,
5. create the final dashboard(s),
6. generate all required intermediate datasets,
7. create the charts/visuals,
8. create the final GTM propositions and decision framework,
9. determine what can and cannot be concluded about H0,
10. leave me with presentation-ready outputs.

You may use Python, pandas, scipy/statsmodels, Plotly, Matplotlib, Streamlit,

DO NOT force Tableau.

I care much more about:

- clarity,
- storytelling,

- defensible analysis,
- beautiful visual hierarchy,
- business usefulness

than about showing technically complicated visualisations.

The dashboard should feel like something a strong product strategy / consultin

=====

A. FIRST: UNDERSTAND THE BUSINESS PROBLEM

=====

The broad project is about Rapido's food-delivery brand Ownly in Hyderabad.

The core market being studied is:

Gachibowli and the surrounding catchment in Hyderabad,
focused primarily on young students and working professionals.

The historical framing of the project is:

"Can Ownly transfer its Bengaluru growth playbook to Gachibowli, and which par

DO NOT reduce this to:

"Do people like Ownly?"

or:

"Should Ownly enter Hyderabad?"

Ownly is already present / claims to be present in Hyderabad.

The strategic question is:

"How large and durable must Ownly's price advantage be to break Swiggy/Zomato

The diagnostic proposition we have been exploring is:

"Price may acquire the customer; assortment and execution may determine whethe

However:

THIS IS A HYPOTHESIS.

DO NOT force the data to support it.

=====

B. IMPORTANT HISTORICAL / STRATEGIC CONTEXT

=====

A large body of secondary research in this repo studies why other Indian food-

- Uber Eats India
- Foodpanda / Ola
- Ola Cafe
- Amazon Food
- TinyOwl
- ONDC / low-price network plays
- Thrive
- DotPe
- Dunzo

- other low-price / direct-order / zero-commission challengers

The synthesis identifies recurring failure mechanisms such as:

M1 – RENTED DEMAND

Price/discounts buy trial but demand collapses when subsidy disappears.

M2 – ATTACKING THE NON-SCARCE SIDE

Restaurants may happily multi-home or accept lower commissions, but restaurant

M3 – NO NEW USE CASE

Same restaurants + similar/slower delivery + cheaper price may not create dura

M4 – RELIABILITY FLOOR

Cheap food delivery still fails if fulfilment, refunds, tracking and support a

M5 – THIN REVENUE ARCHITECTURE

Food delivery economics are structurally difficult; low/zero commission can re

Ownly must NOT be declared a failure simply because previous challengers faile

Instead ask:

"Which historical failure mechanisms are visible in Ownly's Gachibowli operati

=====

C. MANDATORY REPOSITORY AUDIT

=====

BEFORE ANALYSING ANYTHING:

Recursively inspect the repository.

Create:

/final_dashboard/00_repo_inventory.md

The inventory must list:

1. available survey datasets
2. interview transcripts / interview notes
3. survey instruments
4. app-store review datasets
5. Play Store review datasets
6. Reddit/social datasets or coded excerpts
7. LinkedIn/article evidence
8. secondary research
9. Ownly restaurant/user research
10. Uber Eats / Foodpanda / challenger-failure research
11. price audits
12. Swiggy/Zomato/Ownly basket comparisons
13. ETA observations
14. late-night observations
15. restaurant-coverage observations
16. hypothesis documents
17. pre-analysis plans

18. decision logs
19. existing dashboard schemas
20. any existing cleaned/derived data
21. any current Tableau files
22. any existing visual assets or screenshots

For each relevant artifact determine:

- filename/path
- evidence type
- geography
- date
- sample size if applicable
- whether raw / cleaned / derived
- evidence quality
- what question it can answer
- what it CANNOT answer

Do not analyse random unrelated repo files.

=====

D. EVIDENCE HIERARCHY

=====

Keep evidence types distinct.

Use labels such as:

FACT
PRIMARY OBSERVED DATA
SURVEY – STATED BEHAVIOUR
SURVEY – STATED PREFERENCE
INTERVIEW
CONSUMER-GENERATED
COMPANY CLAIM
MEDIA REPORT
ANALYST ESTIMATE
INTERPRETATION
UNKNOWN

Never merge fundamentally different evidence types into one statistic.

Examples:

App reviews $\neq$ population failure rate.

Survey intention $\neq$ actual conversion.

Quoted ETA $\neq$ actual delivery time.

Media claim $\neq$ independent fact.

Bengaluru $\neq$ Hyderabad.

Historical challenger failure $\neq$ proof Ownly will fail.

=====

E. ZERO-FABRICATION RULE

=====

THIS RULE IS ABSOLUTE.

DO NOT fabricate:

- survey responses
- interviews
- fake-door traffic
- conversions
- orders
- restaurant availability
- prices
- ETA
- CAC
- CLV
- retention rate
- market share
- volume share
- EBITDA
- revenue
- burn/order
- margin
- restaurant count
- Ownly economics

If a business metric cannot be calculated from available data, display:

"NOT ESTIMABLE FROM AVAILABLE EVIDENCE"

or

"UNKNOWN"

Do not fill gaps using convenient assumptions.

Scenario modelling is allowed ONLY if visibly labelled:

SCENARIO / SENSITIVITY ANALYSIS – NOT OBSERVED DATA

Never mix scenarios with actual observations.

=====

F. IMPORTANT METHODOLOGICAL ISSUE: H0

=====

Find the project's authoritative H0 definition from the repo.

My understanding is that it originally resembles:

H0:

Among the target Gachibowli population, a Bengaluru-style Ownly proposition do

H1:

The first-order conversion rates differ.

A planned fake-door / behavioural conversion test was not completed.

Therefore:

DO NOT pretend we observed first-order conversion.

If the survey contains Service P vs Service Q concept choices / try-intent que

STATED-PREFERENCE PROXY EVIDENCE

not actual conversion.

The final H_0 panel must distinguish:

BEHAVIOURAL H_0 :

NOT DIRECTLY TESTED if no behavioural experiment exists.

SURVEY / STATED-PREFERENCE ANALOGUE:

Testable using the available P-vs-Q items if they exist.

Use appropriate statistical tests based on the actual instrument.

Report:

- n
- proportions
- 95% CI
- p-value where appropriate
- "cannot reject" vs "reject"

NEVER write:

" H_0 is proven."

Use:

"reject H_0 "

or

"fail to reject H_0 "

where statistically justified.

If sample size is weak, say:

"DIRECTIONAL – INSUFFICIENT POWER"

=====
G. TARGET-POPULATION / AGE ISSUE
=====

Audit the repo for any inconsistency between:

- original 20–30 scope
- later 20–35 scope
- actual age buckets collected in the survey

DO NOT silently fix this.

Create a data-quality note.

If 30–35 respondents cannot be split into age 30 vs 31–35, explicitly state th

Where useful:

- show the strict preregistered population
- show an expanded exploratory population separately

Never blend them without a label.

H. CLEANING AND ANALYSIS

Use the existing cleaning protocol / PAP wherever available.

Do not overwrite raw files.

Create:

```
/final_dashboard/data/raw_manifest.csv
/final_dashboard/data/cleaned_survey.csv
/final_dashboard/data/derived_survey_metrics.csv
/final_dashboard/data/audit_clean.csv
/final_dashboard/data/audit_pairs.csv
/final_dashboard/data/review_theme_summary.csv
/final_dashboard/data/interview_theme_summary.csv
/final_dashboard/data/evidence_matrix.csv
/final_dashboard/data/kpi_table.csv
/final_dashboard/data/marketing_metrics.csv
/final_dashboard/data/hypothesis_results.csv
```

Preserve:

RAW
CLEANED
EXCLUDED

with exclusion_reason.

I. CORE RESEARCH QUESTIONS THE DASHBOARD MUST ANSWER

The dashboard should collectively answer:

1. What exactly is the business problem?
2. How locked-in are Gachibowli customers to incumbents?
3. How important is price?
4. How much recurring saving is required to switch?
5. Does speed matter enough to defeat a lower price?
6. Does reliability matter enough to defeat a lower price?
7. Does restaurant assortment matter enough to defeat a lower price?
8. Is Ownly actually cheaper in the observed audit?
9. Do incumbent discounts/memberships erase Ownly's price advantage?
10. What ETA trade-off accompanies Ownly's saving?

11. Does Ownly have the restaurants people already use?
12. What do actual Ownly users/reviewers complain about?
13. Does the Rapido ecosystem create discovery, or merely theoretical distribu
14. Is late-night absence a visible competitive gap?
15. What happened to previous Indian food-delivery challengers?
16. Which failure mechanisms apply to Ownly?
17. Which failure mechanisms has Ownly genuinely escaped?
18. What is still UNKNOWN?
19. What parts of Bengaluru's GTM should Hyderabad KEEP?
20. What should be ADAPTED?
21. What should be DEPRIORITISED / DROPPED?
22. What should Ownly test next?
23. What does the evidence say about H0?

J. FINAL DASHBOARD ARCHITECTURE

I need the following deliverables.

Do NOT make these visually dense.

Prefer:

- 3-6 strong visuals per screen
- very large headline insight
- few but meaningful KPI cards
- short annotations
- simple charts
- strong whitespace
- one clear takeaway per section

Avoid:

- complicated Sankeys unless truly necessary
- radar charts
- 3D charts
- massive correlation matrices
- overly technical modelling visuals
- chart junk
- excessive colours
- dashboards that look like academic statistics software

Use executive / consulting storytelling.

DASHBOARD 1 – BUSINESS PROBLEM

Purpose:

Explain the entire problem in <30 seconds.

Title concept:

"Can Ownly turn a cheaper first order into a repeat habit in Gachibowli?"

Show:

A. MARKET CONTEXT

- Gachibowli target
- incumbent dominance / membership lock-in from OUR SAMPLE
- Ownly awareness / trial from OUR SAMPLE
- availability context

B. BUSINESS TENSION

Present visually:

CHEAPER FINAL BILL

↓

FIRST TRIAL

↓

?

↓

REPEAT / MAIN APP

Then show the three risks around the "?"

- restaurant availability
- delivery / fulfilment
- incumbent memberships / coupons

C. HISTORICAL WARNING

Small panel:

"Low-price food challengers have repeatedly struggled to convert acquisition i

Use only 2-3 strongest historical examples.

D. CORE DECISION

"Which Bengaluru GTM components should Gachibowli KEEP / ADAPT / DEPRIORITISE?

Do not overcrowd this dashboard with detailed charts.

DASHBOARD 2 – KPI DRIVER TREE

This should clearly answer the faculty requirement:

"Identify important KPIs which drive the input and output of the business."

Build an INPUT → BEHAVIOUR → OUTPUT driver tree.

Potential INPUT KPIs:

PRICE

- Exact-match Price Win Rate
- Median ₹ Saving
- Median % Saving
- Offer Dependence / coupon reversal

ASSORTMENT

- Cross-platform restaurant overlap
- Ownly-only supply observed

- usual-restaurant importance

SERVICE

- Quoted ETA gap
- fulfilment complaint signal
- support/refund complaint signal

DISTRIBUTION

- Recent Rapido use
- Ownly awareness
- Rapido-food discovery

LOCK-IN

- subscription penetration
- multi-homing
- switching threshold

Potential OUTPUT KPIs:

- Ownly awareness
- browse / consideration
- stated trial
- Ownly sample trial
- switching-ready share
- stated post-offer repeat intent
- observed Ownly order frequency if available

Show each KPI with:

VALUE

SAMPLE / BASE

SOURCE

EVIDENCE QUALITY

Example:

81%

INCUMBENT MEMBERSHIP LOCK-IN

n = ...

Survey – Hyderabad target sample

NOT:

81%

LOCK-IN

without context.

Create a visual driver tree showing which inputs influence:

ACQUISITION

and

RETENTION

Do not imply causality unless observed.

The brief asks for 3–7 marketing metrics derived from one or more KPIs.

Create 5–7 defensible derived metrics.

Prioritise metrics we can ACTUALLY calculate.

Candidate metrics to validate against the data:

1. PRICE WIN RATE

Comparable baskets where Ownly has lowest final payable

÷

all valid comparable baskets

2. MEDIAN SAVING

Median of:

cheapest incumbent final payable – Ownly final payable

3. SWITCHING REACH @ ₹X

Respondents whose stated required saving $\leq$ ₹X

÷

eligible respondents

Use actual observed audit median saving as X if defensible.

4. ASSORTMENT BARRIER RATE

Respondents paying the premium / selecting the "usual restaurants" alternative

÷

respondents shown the ₹30 assortment trade-off

5. INCUMBENT LOCK-IN RATE

Subscription holders

÷

eligible target respondents

6. RAPIDO DISCOVERY GAP

Recent Rapido users who have NOT noticed food ordering

÷

recent Rapido users

7. STATED TRIAL-TO-REPEAT INTENT GAP

Likely-to-try proposition

minus

likely-to-continue-after-offer

Clearly label this a STATED-INTENT PROXY, not actual retention.

Potential eighth metric only if valid:

OFFER REVERSAL RATE

Matched baskets where Ownly wins before incumbent discounts

but loses after available incumbent offers

÷

valid matched baskets

Do NOT calculate:

value share

volume share

CAC

CRC

EBITDA

CLV

unless the repo actually contains defensible numerator and denominator data.

If not estimable, create a small panel:

"Important business metrics currently NOT ESTIMABLE"

CAC

CLV

EBITDA

market share

true retention

This is a strength, not a weakness.

DASHBOARD 4 – ANALYSIS: THE ₹30 SWITCHING EQUATION

This should be one of the most memorable visuals.

Use the survey's comparable ₹30 trade-off questions.

Create a visual titled something like:

"WHAT WILL GACHIBOWLI USERS TRADE FOR ₹30?"

Show three very simple horizontal comparisons:

PRICE vs SPEED

PRICE vs RELIABILITY

PRICE vs USUAL RESTAURANTS

The amount must remain constant if that is how the survey was designed.

Annotate with sample size.

The chart should immediately answer:

- Are users willing to wait longer for ₹30?
- Are users willing to accept worse stated reliability for ₹30?
- Are users willing to lose their usual restaurants for ₹30?

Generate a one-line insight based on actual calculated results.

DO NOT hard-code any percentages from notes.

RECOMPUTE FROM RAW DATA.

DASHBOARD 5 – ANALYSIS: PRICE-TO-SWITCH FIT

This dashboard links stated customer requirements with actual observed market

LEFT:

"How much recurring saving do users require to switch?"

Create cumulative switching curve from the survey.

₹10

₹20

₹30

₹50

₹75

₹100+

Keep:

"price alone would not make me switch"

and

"don't know"

separate.

RIGHT:

"What saving did we actually observe?"

Plot observed exact-match Ownly saving vs cheapest incumbent.

Use:

₹ saving

% saving

Then create the key overlay / interpretation:

"Does Ownly's observed saving fall inside the range required to change behavior"

Do not forecast market share.

Call it:

PRICE-TO-SWITCH FIT

not "conversion".

DASHBOARD 6 – ANALYSIS: MARKET REALITY

This dashboard should use the competitor audit.

PRIMARY VISUAL:

FINAL PAYABLE vs QUOTED ETA

X-axis:

final payable ₹

Y-axis:

quoted ETA midpoint

Each mark:

platform × matched basket

Platform:

Ownly

Swiggy

Zomato

Keep it easy to read.

Highlight the strategic quadrants:

LOWER PRICE / FASTER

LOWER PRICE / SLOWER

HIGHER PRICE / FASTER

HIGHER PRICE / SLOWER

Do not overuse colours.

SECONDARY VISUAL:

FEE / BILL WATERFALL

For 2–4 compelling matched baskets show:

food

packaging

platform

delivery

tax

discount

final payable

THIRD VISUAL:

BEFORE OFFER vs AFTER OFFER

If audit captures permit:

show how incumbent coupons/memberships change the winner.

This is strategically important.

Clearly distinguish:

STRUCTURAL / LIST+FEES VIEW

from

ACTUAL WALLET PRICE

Never fabricate a no-discount number if it cannot be observed.

DASHBOARD 7 – ANALYSIS: ASSORTMENT & AVAILABILITY

Show:

1. Restaurant overlap across Ownly / Swiggy / Zomato
2. Ownly-only restaurants observed
3. Incumbent-only restaurants observed
4. local / regional vs chains if available
5. usual-restaurant importance from survey
6. late-night availability by platform

Create a simple platform × daypart heatmap:

Lunch

Dinner

Post-midnight

Only use observed slots.

Do not conclude that post-midnight is a major demand opportunity unless interv

Correct interpretation if demand evidence is missing:

"Late-night availability is an observed supply gap; demand importance remains

DASHBOARD 8 – ANALYSIS: AWARENESS → TRIAL

Build an Ownly sample funnel.

Example stages where data exists:

TARGET SAMPLE

↓

AWARE

↓

OPENED / BROWSED

↓

ORDERED

Use ACTUAL survey data.

Show sample bases at every stage.

If n is tiny, label:

DIRECTIONAL – LOW BASE

Next to this, show:

RAPIDO DISTRIBUTION vs RAPIDO DISCOVERY

For example:

recent Rapido users

vs

users noticing food inside Rapido

vs

Ownly awareness / trial

The strategic question:

"Does Rapido provide real customer discovery, or only theoretical access?"

Do not calculate CAC.

DASHBOARD 9 – ANALYSIS: TRIAL vs RETENTION RISK

Combine survey, reviews and interview evidence.

Potential visuals:

A. Stated trial intent vs stated post-offer repeat intent

B. Review-theme comparison:

general discussion

vs

first-hand Ownly experiences

vs

app-store reviews

Themes:

- price advantage
- price doubt
- fulfilment
- support/refunds
- assortment
- trust/quality

Do NOT present review percentages as order failure rates.

Use exact wording such as:

"share of coded review items mentioning theme"

not:

"% of Ownly orders failing"

C. Interview evidence

Use 3–5 short verbatim quotes only.

Every quote must be verified against original transcript / notes.

Label:

Interview P1 / P2 etc.

Do not invent a quote.

Create a synthesis like:

PRE-ORDER:

Price / savings

SWITCHING:

Restaurant availability

POST-ORDER:

Fulfilment / support

Only if evidence supports it.

DASHBOARD 10 – ANALYSIS: WHY CHALLENGERS FAIL

This should tell the historical story in one screen.

Title:

"WHAT KILLED PREVIOUS FOOD-DELIVERY CHALLENGERS – AND IS OWNLY DIFFERENT?"

Use the strongest defensible examples only.

Potential historical evidence:

UBER EATS INDIA

- India-only SEC financial data
- loss/order vs AOV
- exited due to no path to leadership

FOODPANDA / OLA

- aggressive discounting
- reported order collapse
- high loss vs revenue

ONDC / THRIVE / DIRECT ORDERING

- price / commission advantage
- demand did not necessarily follow restaurant participation
- caveats around subsidy data

Then show five mechanism cards:

M1 RENTED DEMAND

M2 WRONG / NON-SCARCE SIDE

M3 NO NEW USE CASE

M4 RELIABILITY FLOOR

M5 THIN ECONOMICS

Next to each:

Historical evidence

Ownly evidence

Status:

ESCAPED

PARTIALLY ESCAPED

AT RISK

UNKNOWN

Do not state:

"Ownly will fail."

Use:

"Ownly shows / does not show the historical risk signal."

DASHBOARD 11 – EVIDENCE TRIANGULATION

Create a matrix.

ROWS:

Price

Assortment

Speed

Reliability

Support/refunds

Rapido distribution

Membership lock-in

Late-night

Sustainable economics

COLUMNS:

Survey

Interviews

Price audit

App reviews

Reddit/social

Secondary research

Historical challengers

Cell status:

SUPPORTS

CONTRADICTS

MIXED

NO EVIDENCE

The last column:

CURRENT INTERPRETATION

Examples:

STRONG

MODERATE

DIRECTIONAL

UNKNOWN

This dashboard should make it obvious that recommendations are triangulated, n

DASHBOARD 12 – PROPOSITIONS

Turn the findings into proposed GTM propositions.

Do not make generic feature recommendations.

Evaluate possible proposition territories such as:

PRICE

"Same food. Smaller final bill."

PRICE + ASSORTMENT

"The restaurants you already order from, at a meaningfully smaller final bill."

RELIABILITY

"A cheaper order that still turns up when expected."

RAPID0 CROSS-SELL

"Food inside the app you already use."

LOCAL SUPPLY

"Local favourites without inflated online prices."

For each proposition create a card:

PROPOSITION

CUSTOMER JOB

EVIDENCE FOR

EVIDENCE AGAINST

BUSINESS LOGIC

RISKS

CONFIDENCE

CURRENT DECISION:

KEEP

ADAPT

DEPRIORITISE

TEST LATER

The proposition ultimately chosen must come from evidence, not from what sound

DASHBOARD 13 – FINAL GTM DECISION

THIS IS THE EXECUTIVE CONCLUSION.

Structure:

WHO

Which segment appears most promising?

ACQUISITION HOOK

What gets them to consider / try?

PRICE REQUIREMENT

How large does the saving need to be?

SUPPLY REQUIREMENT

What restaurant availability is required?

CHANNEL

What role should Rapido play?

EXPERIENCE GUARDRAIL

What must be "good enough" to avoid churn?

RETENTION

What likely makes trial become repeat?

COMPETITIVE RESPONSE

How can Swiggy/Zomato neutralise Ownly's advantage?

VIABILITY

What business-model questions remain unresolved?

Then final:

KEEP

ADAPT

DEPRIORITISE

TEST NEXT

Do NOT create a fake single-number "Ownly score" unless a pre-registered score

DASHBOARD 14 – HYPOTHESIS DECISION

This must be statistically and methodologically correct.

Show:

ORIGINAL H0

AVAILABLE EVIDENCE

BEHAVIOURAL TEST STATUS

SURVEY PROXY RESULT

STATISTICAL TEST

n

effect / proportions

CI

p-value

Then the conclusion.

Possible wording if supported:

"Survey stated-preference evidence does not provide sufficient evidence to dis

"Behavioural first-order conversion remains untested because the planned fake-

Then explain the more informative decomposed finding:

"Although the bundled propositions may not separate clearly, the attribute-lev

DO NOT twist the results just to produce a rejection.

=====

K. KPI DEFINITIONS

=====

For every KPI / metric create a data dictionary containing:

metric_name

business_question

formula

numerator

denominator

data_source

population

sample_size

evidence_type

limitations

interpretation_rule

Save as:

/final_dashboard/data/metric_dictionary.csv

No KPI should appear in the dashboard unless its definition exists here.

=====

L. STATISTICAL DISCIPLINE

=====
For proportions:

show n/N and 95% CI where useful.

For tiny samples:

use exact / Wilson approaches rather than pretending precision.

For medians:

use medians before means where distributions are skewed.

For survey segmentation:

do not run dozens of meaningless significance tests.

Use segments that matter:

student vs working professional
membership vs no membership
Rapido user vs non-user
Ownly awareness status
frequent vs lower-frequency food orderer
Gachibowli vs broader catchment

Only if sample size permits.

Do not use sophisticated ML models merely because they are available.

=====
M. VISUAL DESIGN RULES
=====

The dashboard must feel:

MODERN
PREMIUM
MINIMAL
CONSULTING-STYLE
STORY-DRIVEN

Not:

DATA-SCIENCE NOTEBOOK
ACADEMIC PAPER
TABLEAU HOMEWORK
POWER BI DEMO

Rules:

1. Every page gets ONE headline finding.
2. Every visual must answer one question.
3. Use whitespace generously.
4. Use a restrained colour system.

5. Use one accent colour for Ownly where appropriate.
6. Keep Swiggy / Zomato visually differentiated but subtle.
7. Avoid rainbow palettes.
8. Avoid more than 6 KPI cards on one screen.
9. Use short annotation call-outs directly on charts.
10. Footnote sample size and evidence source.
11. Prefer:
 - horizontal bars
 - dot plots
 - slope charts
 - simple scatterplots
 - waterfalls
 - funnels
 - heatmaps
 - matrices
 - annotated number cards
12. Avoid:
 - radar charts
 - 3D
 - gauges
 - excessive pie charts
 - complex Sankeys
 - unnecessary dual axes
13. Each dashboard should be understandable in ~20-30 seconds.

=====

N. IMPLEMENTATION PREFERENCE

=====

Prefer a Python-based output unless there is a compelling reason otherwise.

Recommended stack:

Python
pandas
numpy
scipy
statsmodels where needed
Plotly
Streamlit OR a self-contained HTML dashboard

If using Streamlit:

create:

/final_dashboard/app.py
/final_dashboard/pages/...

If using static HTML:

create:

/final_dashboard/index.html

with navigation between dashboard sections.

ALSO export presentation-ready screenshots / images to:

/final_dashboard/exports/

Suggested files:

01_business_problem.png
02_kpi_driver_tree.png
03_marketing_metrics.png
04_switching_equation.png
05_price_switch_fit.png
06_market_reality.png
07_assortment_availability.png
08_awareness_trial.png
09_trial_retention.png
10_challenger_failures.png
11_evidence_matrix.png
12_propositions.png
13_gtm_decision.png
14_hypothesis_decision.png

If PDF export is feasible, also create:

/final_dashboard/Ownly_Gachibowli_GTM_Dashboard.pdf

=====
0. SOURCE TRACEABILITY
=====

Every important dashboard statement must be traceable.

Create:

/final_dashboard/SOURCE_MAP.md

For every headline finding include:

finding
source file
variables / rows
calculation
sample
evidence label
caveat

Example:

Finding:
"X% of target respondents chose the cheaper/slower option."

Source:
survey CSV

Question:
exact question wording

Population:
Hyderabad target respondents

Calculation:
 $n \text{ chose option} / N \text{ answered}$

Do this for every headline.

=====

P. DECISION DISCIPLINE

=====

Final recommendations must separate:

WHAT THE DATA SHOWS

WHAT WE INTERPRET

WHAT WE RECOMMEND

WHAT REMAINS UNKNOWN

Do not blur these four categories.

Example:

DATA:
70% selected restaurant assortment over ₹30 saving.

INTERPRETATION:
Usual—restaurant availability appears to be a stronger switching constraint th

RECOMMENDATION:
Prioritise penetration of frequently ordered Gachibowli restaurants before max

UNKNOWN:
Actual order conversion uplift from expanding assortment.

=====

Q. EXPECTED STRATEGIC STORY

=====

Do NOT force this story, but investigate whether the evidence supports somethi

"Ownly does not need to beat Swiggy/Zomato on everything.

Its opportunity may be to create a meaningfully smaller recurring final bill o

Historical challenger research should then be used to ask:

"Has Ownly created a structural advantage, or is it merely another price-led c

Possible final structure:

PRICE
can create trial

ASSORTMENT

can determine switching

FULFILMENT / SUPPORT

can determine repeat

RAPIDO

can reduce discovery friction

UNIT ECONOMICS

remain an unresolved strategic constraint

Again:

ONLY write this if the evidence genuinely supports it.

=====

R. EXECUTION ORDER

=====

Do this autonomously.

PHASE 1

Inventory repo.

PHASE 2

Locate authoritative scope, H_0 , hypotheses and PAP.

PHASE 3

Create source/evidence map.

PHASE 4

Clean survey and determine valid analysis populations.

PHASE 5

Clean competitor audit.

PHASE 6

Aggregate review/social themes.

PHASE 7

Code / aggregate interview findings already available.

PHASE 8

Extract challenger-failure evidence.

PHASE 9

Compute KPIs.

PHASE 10

Compute marketing metrics.

PHASE 11

Run hypothesis analysis.

PHASE 12

Create visual storyboards.

PHASE 13

Build dashboards.

PHASE 14

QA every number against the source.

PHASE 15

Export presentation assets.

PHASE 16

Write final executive interpretation.

DO NOT stop after planning.

DO NOT ask me to manually calculate data you can calculate.

DO NOT ask me which visual I prefer unless there is a genuinely blocking decision.

Make reasonable design decisions yourself and document them.

=====

S. FINAL DOCUMENTATION

=====

Create:

/final_dashboard/README.md

It must contain:

1. what was built
2. dashboard structure
3. how to run it
4. source datasets used
5. analysis population
6. cleaning performed
7. KPI definitions
8. marketing metric definitions
9. statistical methods
10. H0 result
11. key insights
12. GTM recommendation
13. limitations
14. unresolved unknowns
15. what would need to be tested next in a real company

Also create:

/final_dashboard/EXECUTIVE_SUMMARY.md

Maximum 2 pages.

It should answer:

BUSINESS PROBLEM

WHAT WE FOUND

WHY IT MATTERS

WHAT OWNLY SHOULD KEEP

WHAT OWNLY SHOULD ADAPT

WHAT SHOULD BE DEPRIORITISED

H0 RESULT

WHAT WE STILL DO NOT KNOW

=====

T. FINAL QUALITY GATE

=====

Before declaring the work complete, review EVERY dashboard and ask:

1. Can someone understand the business question in <10 seconds?
2. Does every large number show its denominator or sample?
3. Is survey intent clearly differentiated from actual behaviour?

3. usable datasets found,
4. conflicts/gaps found,

5. exact dashboards you will now build.

Then immediately continue implementation without waiting for approval unless y

One change I strongly recommend from our earlier thinking: make Claude build the **H₀ dashboard separately from the GTM decision dashboard**. Your original H₀ concerns first-order conversion, but because the fake door was not run, the survey can only give a stated-preference analogue. Keeping those separate prevents the final presentation from accidentally claiming that survey preference was actual conversion. Your existing project documents also explicitly require evidence labels, separation of intent from behaviour, and no fabricated CAC/CLV/EBITDA.  project_context

The challenger research is especially useful for Dashboard 10 because you already have unusually strong evidence: Uber's India-specific SEC economics, Foodpanda's loss/discount/delivery-cost history, direct-order/ONDC cases, incumbent unit economics, and an Ownly-vs-five-failure-mechanisms synthesis.  A_ubereats_foodpanda

 D_synthesis_why_challengers_fail

The final result should therefore feel like **one GTM argument supported by many evidence types**, not fourteen unrelated analytics pages.

Yesterday 9:44 PM

In the survey questions, we are asking: would they pay ₹260 delivered on time versus ₹230 and ₹260 delivered on time, and regular restaurants versus ₹230 delivered a bit late? The question here is a common question. The result we got was that 67% chose to stay with the actual restaurants they order from instead of ₹30.

If the difference is ₹50 or ₹70, they would still go for the difference, right? They would go for a ₹10 or lesser option. How did we fix it on the ₹30 option? If we tell people, "Choose to stay, go for regular restaurants than

Show more 

Worked for 46s >

You're right: **the ₹30 result does not tell us what happens at ₹50, ₹70, or ₹100**. That is the most important limitation to state clearly.

The ₹30 question was designed as a **controlled benchmark**, not as a full willingness-to-pay curve. In the survey, the same ₹30 difference was deliberately held constant while

only the non-price attribute changed—speed, reliability, or restaurant availability. That lets you compare **which attribute people defend most strongly for the exact same monetary sacrifice.**  Survey_v6_Google_Form_Build_Gui...

So the defensible conclusion is:

“At a ₹30 premium, respondents were more willing to pay extra to keep their usual restaurants than to gain faster delivery or better reliability.”

Not:

“People will always choose their usual restaurants regardless of price.”

And not:

“₹30 is the exact value of restaurant assortment.”

Why ₹30 was reasonable in the first place

There are three defensible reasons.

First, ₹30 was not pulled completely out of nowhere. Your research had Ownly's Bengaluru delivery fee repeatedly reported at around ₹30, although the evidence was contradictory and Hyderabad-specific delivery fees were unknown. The price-design note explicitly treated ₹30 as a central market anchor, while also flagging it as an assumption requiring audit confirmation.  market_price_anchors

Second, ₹30 is meaningful relative to your target basket. Your design research treated roughly ₹150–₹300 as a plausible single-person meal range. So a ₹30 difference is about **10–20% of the basket**, large enough to matter but not so large that it automatically dominates every other attribute.  market_price_anchors

Third, and most importantly, **the same ₹30 was held constant across all three trade-offs.** That is what gives the experiment its comparative power. If speed had ₹10, reliability ₹30, and assortment ₹50, you could not tell whether differences came from the attribute or from the money.

That is the strongest methodological defense.

What your 67% actually means

Suppose the question was:

- ₹260, most of your usual restaurants
- ₹230, only a few of your usual restaurants

and **67% chose ₹260.**

Then, within that hypothetical choice:

67% were willing to sacrifice at least ₹30 to preserve broad access to their usual restaurants.

That is a useful **lower-bound** interpretation.

For those respondents, the value they place on the difference between “most usual restaurants” and “only a few” is **at least ₹30 in this context**.

But you do **not** know whether their break point is:

- ₹31
- ₹45
- ₹50
- ₹70
- ₹100

because you never varied the price gap.

So the correct dashboard language is:

“67% accepted a ₹30 premium to retain most of their usual restaurants.”

or:

“At ₹30, restaurant assortment outweighed price for 67% of respondents.”

Do not write:

“Restaurant assortment is worth ₹30.”

because many of them may have paid ₹50 or ₹70 too.

Your exact concern is basically a demand-curve problem

Imagine the premium for keeping your restaurants changes:

Premium for usual restaurants	Share choosing usual restaurants
₹10	?
₹30	67%
₹50	?
₹70	?
₹100	?

You only measured **one point on that curve**.

You don't know the rest.

Usually, we would expect the share choosing assortment to decrease as the price premium rises, but your survey did not estimate the slope. You should not invent it.

If you had designed the ideal experiment from the beginning, you would randomly vary the premium across respondents—for example ₹10 / ₹30 / ₹50 / ₹70—and estimate the choice probability or WTP curve. Your pre-analysis plan itself says that stronger rupee-value claims require a proper choice model and a significant price coefficient; otherwise the fallback is to report the individual task shares descriptively.  M_pre_analysis_plan

Then what is the switching-threshold question useful for?

You *do* have a second question:

"How much lower would the final amount need to be, every time, for you to make a different app your main one?"

with:

₹10 / ₹20 / ₹30 / ₹50 / ₹75 / ₹100+ / price alone wouldn't make me switch.

That question gives you a **general switching-price threshold**.

But it is not the same as:

"How much would you pay to preserve your usual restaurants?"

So use the two questions together, but don't merge them mathematically.

The story becomes:

Trade-off question:

"At ₹30, 67% defended their usual restaurants."

Switching-threshold question:

"Separately, the distribution of required savings shows how much recurring saving respondents say they need before switching their main app."

Together, they tell you:

Price matters, but price alone is not sufficient; restaurant availability can block switching even at a meaningful ₹30 saving.

That is defensible.

There is actually a useful cross-tab you can run now

Without collecting new data, you can split respondents by their own general switching threshold.

For example:

- respondents needing $\leq ₹30$ to switch
- respondents needing ₹50+
- respondents saying price alone wouldn't make them switch

Then check what each group chose in the **restaurant ₹30 trade-off**.

This does **not** tell you what would happen at a ₹50 restaurant premium.

But it gives a richer insight.

For example, if even respondents who say they are highly price-sensitive still choose their usual restaurants at ₹30, that's strong evidence that assortment is a serious constraint.

If people requiring ₹50+ to switch are disproportionately the ones choosing restaurants, that also helps explain heterogeneity.

Label this **exploratory cross-tab**, not a new experiment.

How I would defend this in front of your professor

Say:

"We fixed the monetary difference at ₹30 deliberately. The purpose of these questions was not to estimate the exact rupee value of speed, reliability, or restaurant assortment. It was to compare those attributes on a common monetary benchmark. ₹30 was chosen as a market-plausible amount anchored around Ownly's reported Bengaluru delivery fee and a realistic ₹150–₹300 single-person food basket. By keeping the same ₹30 across all three tasks, we isolate which non-price attribute respondents are least willing to trade away. Therefore, when 67% select their usual restaurants despite paying ₹30 more, the correct interpretation is that assortment dominates a ₹30 saving in this scenario—not that assortment will dominate at ₹50 or ₹70. The exact break-even value was not identified by this survey."  [market_price_anchors](#)

That is a strong answer because it doesn't overclaim.

And I would rename the dashboard metric

Don't call it:

Restaurant importance = 67%

Call it:

Assortment Premium Acceptance @ ₹30

67% chose most of their usual restaurants despite a ₹30 higher final bill.

Then directly underneath in smaller text:

Measured at one price point only; threshold above ₹30 is unknown.

Likewise:

Speed Trade-off @ ₹30

and

Reliability Trade-off @ ₹30

Then your comparative visual becomes methodologically clean:

At the same ₹30 sacrifice, respondents defended restaurant assortment more strongly than speed or reliability.

That is the real reason the ₹30 design is valuable. It is a **common ruler**, not a universal threshold.

Sources

There is also a question in the survey asking how much the difference should be if you have to consider switching from one standard restaurant to another. What is the data from that question? What should the minimum difference be to switch between apps?

Worked for 54s >

Yes. This question is actually much more useful for deciding the **price threshold** than the fixed ₹30 trade-off question.

The exact survey question is:

“Think of a typical order of yours. How much lower would the final amount need to be, every time, for you to make a different app your main one?”

So this is asking about **switching the primary delivery app**, not switching restaurants.

For the current **Hyderabad 20–35 sample**, $n = 27$, the responses are:

Required recurring saving	Respondents	% of sample	Cumulative share willing to switch at this saving or less
₹10	3	11%	11%
₹20	2	7%	19%
₹30	5	19%	37%
₹50	4	15%	52%
₹75	3	11%	63%
₹100 or more	5	19%	—
Price alone wouldn't make me switch	2	7%	—
Don't know	3	11%	—

This gives you a much stronger conclusion than simply saying “₹30 matters.”

The important number is ₹50

If your question is:

“What recurring price difference appears necessary to make at least half of our current Hyderabad sample consider another app as their main app?”

the answer is:

Approximately ₹50 per typical order.

At:

₹30 saving → only 37% of the current sample say that would be enough.

But by:

₹50 saving → 52% say ₹50 or less would be sufficient.

So ₹50 is approximately the **median stated switching threshold** in this sample.

And this gets even more interesting if I restrict it to the actual **Gachibowli-only 20–35 sample, n = 21**:

Saving	Cumulative switching reach
₹10	10%

Saving	Cumulative switching reach
₹20	19%
₹30	43%
₹50	62%
₹75	76%

So in Gachibowli specifically, the same broad conclusion holds:

₹30 is below the majority switching threshold; ₹50 crosses it.

Even if you use the stricter **Hyderabad 20–29** population to stay closer to your originally registered age scope, ₹50 still crosses 50%:

₹30 → 37.5%

₹50 → 54.2%

That consistency makes ₹50 a much more defensible number than choosing it arbitrarily.

But be very precise about what ₹50 means

Don't say:

"₹50 will make customers switch."

You haven't measured actual switching.

Say:

"₹50 emerges as the approximate median stated recurring saving required to consider making another delivery app the respondent's main app."

Three important words:

stated

recurring

main app

The "every time" wording is especially useful because this isn't asking about a ₹100 first-order coupon. It asks about a **persistent price advantage**.

That distinction is extremely important for Ownly.

Now connect this with your ₹30 restaurant question

This is where your analysis becomes genuinely interesting.

You have two separate measurements.

Measurement 1 — general app-switching threshold

At ₹30 recurring saving:

37% Hyderabad say that is sufficient to change their main app.

At ₹50:

52% say it is sufficient.

Therefore:

₹30 does not appear large enough to unlock majority-level stated switching.

Measurement 2 — restaurant-assortment trade-off

At exactly ₹30:

roughly **two-thirds** chose to retain most/usual restaurants instead of taking the cheaper restricted-selection option.

Therefore:

Even a ₹30 saving is not sufficient to compensate many respondents for losing access to their usual restaurants.

Put these together:

Price matters—but the advantage probably needs to be closer to ₹50 than ₹30 to move the median customer, and it cannot come at the cost of the restaurants they already use.

That's a much stronger GTM finding.

This also fixes your earlier ₹30 problem

You were asking:

“Why exactly ₹30? What if it were ₹50 or ₹70?”

Now you don't need to pretend ₹30 is the optimal price difference.

Instead say:

₹30 was the common experimental benchmark used to compare speed, reliability and assortment.

But separately:

the switching-threshold question tells us the monetary magnitude consumers say they need.

And that second question suggests:

₹50 is the first observed threshold where a majority of the current target sample says the recurring saving could be enough to change their main delivery app.

So your two questions serve different purposes:

Question	What it tells us
Fixed ₹30 trade-offs	Which attribute is hardest to sacrifice for the same amount of money?
₹10–₹100+ switching threshold	How large does a recurring saving need to become before app-switching becomes plausible?

That's the methodological defense.

This should become a major dashboard visual

I'd call it:

"How much cheaper must Ownly be to break app lock-in?"

Use a cumulative staircase or horizontal curve:

₹10 → 11%

₹20 → 19%

₹30 → 37%

₹50 → 52% ← MAJORITY THRESHOLD

₹75 → 63%

Then beside it put a vertical marker:

Observed Ownly saving

Median ₹_____

from your actual Swiggy/Zomato/Ownly audit.

This creates perhaps the most business-useful metric in the project:

PRICE–SWITCH FIT

Is Ownly's actual recurring saving $\geq$ the ~₹50 stated median switching threshold?

If your audit says Ownly usually saves ₹20–₹30, then the proposition may be attractive but **not strong enough to break main-app habit for most respondents**.

If the audit consistently shows ₹50–₹70 recurring savings, then the evidence becomes much more compelling.

And if the saving exists only before Swiggy/Zomato coupons, you have another critical insight:

Structural price advantage $\neq$ wallet-level switching advantage.

So for the final project, I would use **₹50—not ₹30—as the central stated switching benchmark**, while keeping ₹30 exclusively as the **controlled trade-off benchmark** for speed/reliability/assortment.
